

# LM5113 80-V, 1.2-A, 5-A, Half Bridge GaN Driver (NRND)

*Not Recommended for New Designs*

## 1 Features

- Independent High-Side and Low-Side TTL Logic Inputs
- 1.2 A / 5 A Peak Source / Sink Current
- High-Side Floating Bias Voltage Rail Operates up to 100 VDC
- Internal Bootstrap Supply Voltage Clamping
- Split Outputs for Adjustable Turnon/Turnoff Strength
- 0.6-Ω / 2.1-Ω Pulldown / Pullup Resistance
- Fast Propagation Times (28 ns Typical)
- Excellent Propagation Delay Matching (1.5 ns Typical)
- Supply Rail Undervoltage Lockout
- Low Power Consumption

## 2 Applications

- Current Fed Push-Pull Converters
- Half and Full-Bridge Converters
- Synchronous Buck Converters
- Two-Switch Forward Converters
- Forward With Active Clamp Converters

## 3 Description

The LM5113 device is designed to drive both the high-side and the low-side enhancement mode Gallium Nitride (GaN) FETs in a synchronous buck or a half bridge configuration. The floating high-side driver is capable of driving a high-side enhancement mode GaN FET operating up to 100 V. The high-side bias voltage is generated using a bootstrap technique and is internally clamped at 5.2 V, which prevents the gate voltage from exceeding the maximum gate-source voltage rating of enhancement mode GaN FETs. The inputs of the LM5113 are TTL logic compatible, and can withstand input voltages up to 14 V regardless of the VDD voltage. The LM5113 has split gate outputs, providing flexibility to adjust the turnon and turnoff strength independently.

The LMG1205 is an enhancement over the LM5113. The LMG1205 takes the design of the LM5113 and includes start-up logic, level shifter, and power-off Vgs clamp enhancements to provide a more robust solution.

In addition, the strong sink capability of the LM5113 maintains the gate in the low state, preventing unintended turnon during switching. The LM5113 can operate up to several MHz. The LM5113 is available in a standard WSON-10 pin package and a 12-bump DSBGA package. The WSON-10 pin package contains an exposed pad to aid power dissipation. The DSBGA package offers a compact footprint and minimized package inductance.

### Device Information<sup>(1)</sup>

PART NUMBER	PACKAGE	BODY SIZE (NOM)
LM5113	WSON (10)	4.00 mm × 4.00 mm
	DSBGA (12)	2.00 mm × 2.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

### Pin Functions

PIN			TYPE <sup>(1)</sup>	DESCRIPTION
NAME	WSON	DSBGA		
VDD	1	A3, C4 <sup>(2)</sup>	P	5-V Positive gate drive supply: locally decouple to VSS using low ESR/ESL capacitor located as close to the IC as possible.
HB	2	D3	P	High-side gate driver bootstrap rail: connect the positive terminal of the bootstrap capacitor to HB and the negative terminal to HS. The bootstrap capacitor should be placed as close to the IC as possible.
HOH	3	D2	O	High-side gate driver turnon output: connect to the gate of high-side GaN FET with a short, low inductance path. A gate resistor can be used to adjust the turnon speed.
HOL	4	D1	O	High-side gate driver turnoff output: connect to the gate of high-side GaN FET with a short, low inductance path. A gate resistor can be used to adjust the turnoff speed.
HS	5	C1, D4 <sup>(2)</sup>	P	High-side GaN FET source connection: connect to the bootstrap capacitor negative terminal and the source of the high-side GaN FET.
HI	6	B4	I	High-side driver control input. The LM5113 inputs have TTL type thresholds. Unused inputs should be tied to ground and not left open.
LI	7	A4	I	Low-side driver control input. The LM5113 inputs have TTL type thresholds. Unused inputs should be tied to ground and not left open.
VSS	8	A2	G	Ground return: all signals are referenced to this ground.
LOL	9	A1	O	Low-side gate driver sink-current output: connect to the gate of the low-side GaN FET with a short, low inductance path. A gate resistor can be used to adjust the turnoff speed.
LOH	10	B1	O	Low-side gate driver source-current output: connect to the gate of high-side GaN FET with a short, low inductance path. A gate resistor can be used to adjust the turnon speed.
Exposed Pad	EP	—	—	Exposed pad: TI recommends that the exposed pad on the bottom of the package be soldered to ground plane on the printed-circuit board to aid thermal dissipation.

**7 Detailed Description****7.1 Overview**

The LM5113 is a high frequency high- and low- side gate driver for enhancement mode Gallium Nitride (GaN) FETs in a synchronous buck or a half bridge configuration. The floating high-side driver is capable of driving a high-side enhancement mode GaN FET operating up to 100 V. The high-side bias voltage is generated using a bootstrap technique and is internally clamped at 5.2 V, which prevents the gate voltage from exceeding the maximum gate-source voltage rating of enhancement mode GaN FETs. The LM5113 has split gate outputs with strong sink capability, providing flexibility to adjust the turnon and turnoff strength independently.

The LM5113 can operate up to several MHz, and available in a standard WSON-10 pin package and a 12-bump DSBGA package. The WSON-10 pin package contains an exposed pad to aid power dissipation. The DSBGA package offers a compact footprint and minimized package inductance.

**7.2 Functional Block Diagram**

Copyright © 2017, Texas Instruments Incorporated

**7.3 Feature Description****7.3.1 Input and Output**

The inputs are independently controlled with TTL input thresholds, and can withstand voltages up to 14 V regardless of the VDD voltage, which means it could be directly connected to the outputs of PWM controllers with up to 14-V power supply, saving a buffer stage between output of higher-voltage powered controller, for example LM5025 with 10 V, and input of the LM5113.

The output pulldown and pullup resistance of LM5113 is optimized for enhancement mode GaN FETs to achieve high frequency and efficient operation. The 0.6-Ω pulldown resistance provides a robust low impedance turnoff path necessary to eliminate undesired turnon induced by high dv/dt or high di/dt. The 2.1-Ω pullup resistance helps reduce the ringing and over-shoot of the switch node voltage. The split outputs of the LM5113 offer flexibility to adjust the turnon and turnoff speed by independently adding additional impedance in either the turnon path, the turnoff path, or both.

## Feature Description (continued)

It is very important that the input signal of the two channels HI and LI, which has logic compatible threshold and hysteresis, must be tied to either VDD or VSS if they are not used. This inputs must not be left floating.

Additionally, the input signals avoid pulses shorter than 3 ns by using the input filter to the HI and LI input pins. The values and part numbers of the circuit components are shown in the [Figure 16](#).

**Figure 16. Input Filter 1 (High-Side Input Filter)**

If short pulses or short delays are required, the circuit in [Figure 17](#) is recommended.

Copyright © 2017, Texas Instruments Incorporated

**Figure 17. Input Filter 1 for Short Pulses (High-Side Input Filter)**

### 7.3.2 Start-Up and UVLO

The start-up voltage sequencing for this device is as follows: VDD voltage first, with the VIN voltage present thereafter.

The LM5113 requires an external bootstrap diode with a 20-Ω series resistor to charge the high-side supply on a cycle-by-cycle basis. The recommended bootstrap diode options are BAT46, BAT41, or LL4148.

The LM5113 has an Undervoltage Lockout (UVLO) on both the VDD and bootstrap supplies. When the VDD voltage is below the threshold voltage of 3.8 V, both the HI and LI inputs are ignored, to prevent the GaN FETs from being partially turned on. Also if there is insufficient VDD voltage, the UVLO will actively pull the LOL and HOL low. When the HB to HS bootstrap voltage is below the UVLO threshold of 3.2 V, only HOL is pulled low. Both UVLO threshold voltages have 200 mV of hysteresis to avoid chattering.

**Table 1. VDD UVLO Feature Logic Operation**

CONDITION ( $V_{HB-HS} > V_{HBR}$ for all cases below)	HI	LI	HO	LO

$V_{HB-HS} < V_{HBR} - V_{HBH}$ after device start-up	L	L	L	L

**7.3.3 HS Negative Voltage and Bootstrap Supply Voltage Clamping**

Due to the intrinsic feature of enhancement mode GaN FETs, the source-to-drain voltage of the bottom switch, is usually higher than a diode forward voltage drop when the gate is pulled low. This will cause negative voltage on HS pin. Moreover, this negative voltage transient will be even worse, considering layout and device drain/source parasitic inductances. With high side driver using the floating bootstrap configuration, Negative HS voltage can lead to an excessive bootstrap voltage which can damage the high-side GaN FET. The LM5113 solves this problem with an internal clamping circuit that prevents the bootstrap voltage from exceeding 5.2 V typical.

**7.3.4 Level Shift**

The level shift circuit is the interface from the high-side input to the high-side driver stage which is referenced to the switch node (HS). The level shift allows control of the HO output which is referenced to the HS pin and provides excellent delay matching with the low-side driver. Typical delay matching between LO and HO is around 1.5 ns.

**7.4 Device Functional Modes**

Table 3 shows the device truth table.

## 8 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application Information

To operate GaN transistors at very high switching frequencies and to reduce associated switching losses, a powerful gate driver is employed between the PWM output of controller and the gates of the GaN transistor. Also, gate drivers are indispensable when it is impossible for the PWM controller to directly drive the gates of the switching devices. With the advent of digital power, this situation is often encountered because the PWM signal from the digital controller is often a 3.3-V logic signal which cannot effectively turn on a power switch. Level shift circuit is required to boost the 3.3-V signal to the gate-drive voltage (such as 12 V) in order to fully turn on the power device and minimize conduction losses. Traditional buffer drive circuits based on NPN/PNP bipolar transistors in totem-pole arrangement prove inadequate with digital power because they lack level-shifting capability. Gate drivers effectively combine both the level-shifting and buffer-drive functions. Gate drivers also find other needs such as minimizing the effect of high-frequency switching noise (by placing the high-current driver IC physically close to the power switch), driving gate-drive transformers and controlling floating power-device gates, reducing power dissipation and thermal stress in controllers by moving gate charge power losses from the controller into the driver.

The LM5113 is a MHz high- and low-side gate driver for enhancement mode Gallium Nitride (GaN) FETs in a synchronous buck or a half bridge configuration. The floating high-side driver is capable of driving a high-side enhancement mode GaN FET operating up to 100 V. The high-side bias voltage is generated using a bootstrap technique and is internally clamped at 5.2 V, which prevents the gate voltage from exceeding the maximum gate-source voltage rating of enhancement mode GaN FETs. The LM5113 has split gate outputs with strong sink capability, providing flexibility to adjust the turnon and turnoff strength independently.

### 8.2 Typical Application

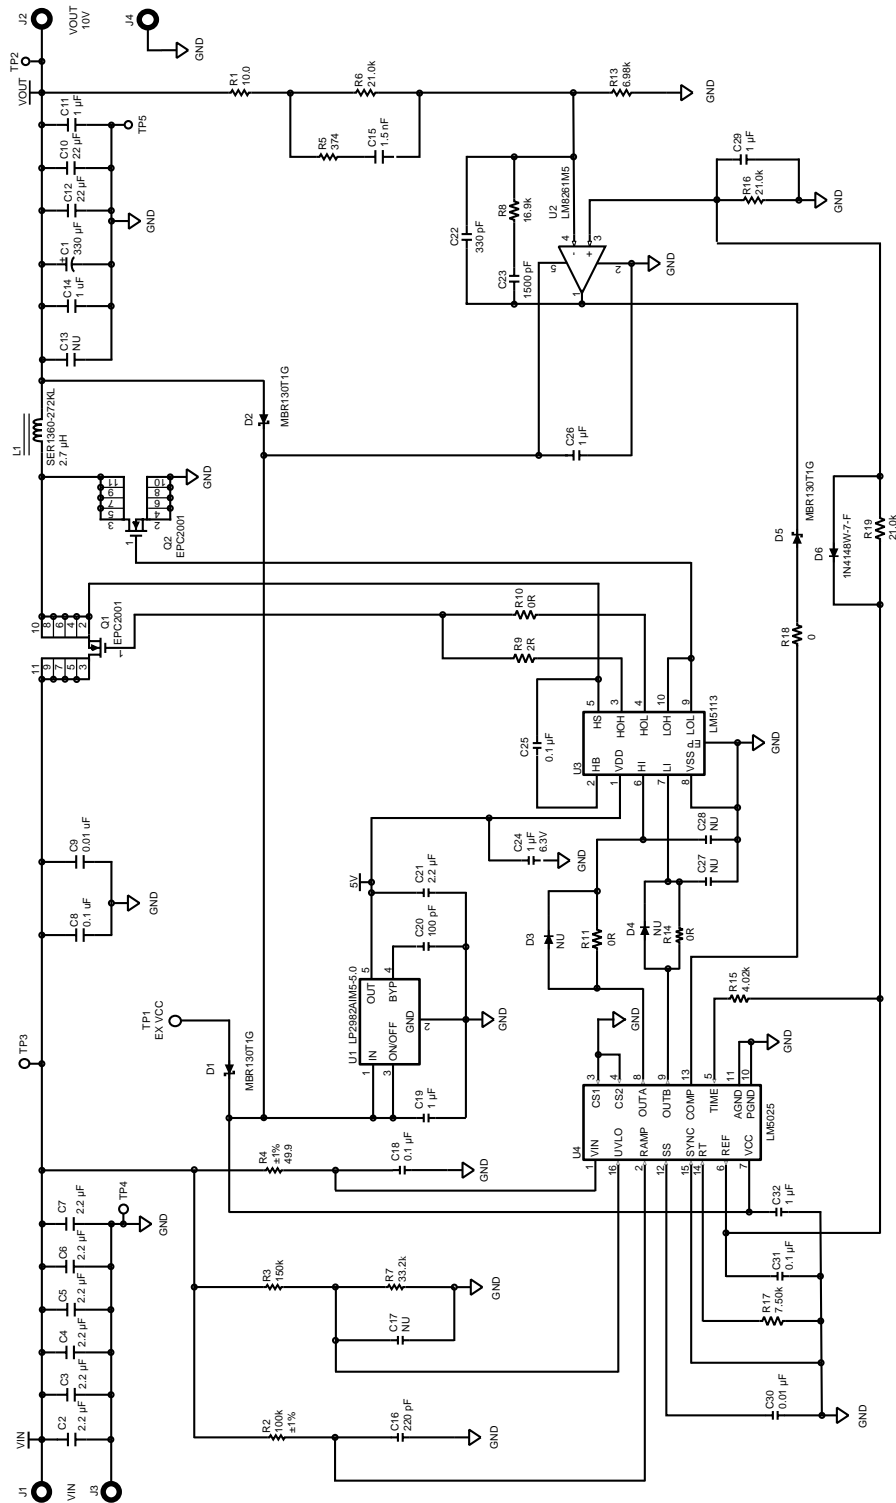

The circuit in [Figure 18](#) shows a synchronous buck converter to evaluate LM5113. Detailed synchronous buck converter specifications are listed in [Design Requirements](#). The active clamping voltage mode controller LM5025 is used for close-loop control and generates the PWM signals of the buck switch and the synchronous switch. For more information, refer to the [Related Documentation](#) section.

# LM5113

SNVS725H –JUNE 2011–REVISED JANUARY 2018

www.ti.com

## Typical Application (continued)

Input 15 V to 60 V, output 10 V, 800 kHz

**Figure 18. Application Circuit**

## Typical Application (continued)

### 8.2.1 Design Requirements

Table 4 lists the design requirements for the typical application.

**Table 4. Design Parameters**

PARAMETER	SPECIFICATION
Input operating range	15 – 60 V
Output voltage	10 V
Output current, 48-V input	10 A
Output current, 60-V input	7 A
Efficiency at 48 V, 10 A	>90%
Frequency	800 kHz

### 8.2.2 Detailed Design Procedure

This procedure outlines the design considerations of LM5113 in a synchronous buck converter with enhancement mode Gallium Nitride (GaN) FET. Refer to Figure 18 for component names and network locations. For additional design help, see [Related Documentation](#).

#### 8.2.2.1 VDD Bypass Capacitor

The VDD bypass capacitor provides the gate charge for the low-side and high-side transistors and to absorb the reverse recovery charge of the bootstrap diode. The required bypass capacitance can be calculated with Equation 1.

$$C_{VDD} > \frac{Q_{gH} + Q_{gL} + Q_{rr}}{\Delta V} \quad (1)$$

$Q_{gH}$  and  $Q_{gL}$  are gate charge of the high-side and low-side transistors respectively.  $Q_{rr}$  is the reverse recovery charge of the bootstrap diode, which is typically around 4 nC.  $\Delta V$  is the maximum allowable voltage drop across the bypass capacitor. A 0.1-μF or larger value, good-quality, ceramic capacitor is recommended. The bypass capacitor should be placed as close to the pins of the IC as possible to minimize the parasitic inductance.

#### 8.2.2.2 Bootstrap Capacitor

The bootstrap capacitor provides the gate charge for the high-side switch, DC bias power for HB undervoltage lockout circuit, and the reverse recovery charge of the bootstrap diode. The required bypass capacitance can be calculated with Equation 2.

$$C_{BST} > \frac{Q_{gH} + I_{HB} \times t_{ON} + Q_{rr}}{\Delta V} \quad (2)$$

$I_{HB}$  is the quiescent current of the high-side driver.  $t_{on}$  is the maximum on-time period of the high-side transistor. A good-quality, ceramic capacitor should be used for the bootstrap capacitor. TI recommends placing the bootstrap capacitor as close to the HB and HS pins as possible.

#### 8.2.2.3 Power Dissipation

The power consumption of the driver is an important measure that determines the maximum achievable operating frequency of the driver. It should be kept below the maximum power dissipation limit of the package at the operating temperature. The total power dissipation of the LM5113 is the sum of the gate driver losses and the bootstrap diode power loss.

The gate driver losses are incurred by charge and discharge of the capacitive load. It can be approximated as:

$$P = (C_{LoadH} + C_{LoadL}) \times V_{DD}^2 \times f_{SW} \quad (3)$$

$C_{LoadH}$  and  $C_{LoadL}$  are the high-side and the low-side capacitive loads, respectively. It can also be calculated with the total input gate charge of the high-side and the low-side transistors as:

$$P = (Q_{gH} + Q_{gL}) \times V_{DD} \times f_{SW} \quad (4)$$

**LM5113**

SNVS725H–JUNE 2011–REVISED JANUARY 2018

www.ti.com

There are some additional losses in the gate drivers due to the internal CMOS stages used to buffer the LO and HO outputs. The following plot shows the measured gate driver power dissipation versus frequency and load capacitance. At higher frequencies and load capacitance values, the power dissipation is dominated by the power losses driving the output loads and agrees well with the above equations. This plot can be used to approximate the power losses due to the gate drivers.

Gate Driver Power Dissipation (LO+HO), VDD = +5 V

**Figure 19. Neglecting Bootstrap Diode Losses**

The bootstrap diode power loss is the sum of the forward bias power loss that occurs while charging the bootstrap capacitor and the reverse bias power loss that occurs during reverse recovery. Because each of these events happens once per cycle, the diode power loss is proportional to the operating frequency. Larger capacitive loads require more energy to recharge the bootstrap capacitor resulting in more losses. Higher input voltages ( $V_{IN}$ ) to the half bridge also result in higher reverse recovery losses.

The following two plots illustrate the forward bias power loss and the reverse bias power loss of the bootstrap diode respectively. The plots are generated based on calculations and lab measurements of the diode reverse time and current under several operating conditions. The plots can be used to predict the bootstrap diode power loss under different operating conditions.

The Load of High-Side Driver is a GaN FET with Total Gate Charge of 10 nC.

**Figure 20. Forward Bias Power Loss of Bootstrap Diode  $V_{IN} = 50$  V**

The Load of High-Side Driver is a GaN FET with Total Gate Charge of 10 nC.

**Figure 21. Reverse Recovery Power Loss of Bootstrap Diode  $V_{IN} = 50$  V**

The sum of the driver loss and the bootstrap diode loss is the total power loss of the IC. For a given ambient temperature, the maximum allowable power loss of the IC can be defined as [Equation 5](#).

$$P = \frac{(T_J - T_A)}{\theta_{JA}} \quad (5)$$

## 8.2.3 Application Curves

### Conditions:

Input Voltage = 48 V DC, Load Current = 5 A

### Traces:

Top Trace: Gate of Low-Side eGaN FET, Volt/div = 2 V

Bottom Trace: LI of LM5113, Volt/div = 5 V

Bandwidth Limit = 600 MHz

Horizontal Resolution = 0.2  $\mu$ s/div

### Conditions:

Input Voltage = 48 V DC,

Load Current = 10 A

### Traces:

Trace: Switch-Node Voltage, Volts/div = 20 V

Bandwidth Limit = 600 MHz

Horizontal Resolution = 50 ns/div

**Figure 23. Switch-Node Voltage**

## 9 Power Supply Recommendations

The recommended bias supply voltage range for LM5113 is from 4.5 V to 5.5 V. The lower end of this range is governed by the internal undervoltage lockout (UVLO) protection feature of the VDD supply circuit. The upper end of this range is driven by the 7-V absolute maximum voltage rating of the VDD or the GaN transistor gate breakdown voltage limit, whichever is lower. TI recommends keeping a proper margin to allow for transient voltage spikes.

The UVLO protection feature also involves a hysteresis function. This means that once the device is operating in normal mode, if the VDD voltage drops, the device continues to operate in normal mode as far as the voltage drop does not exceed the hysteresis specification, VDDH. If the voltage drop is more than hysteresis specification, the device shuts down. Therefore, while operating at or near the 4.5-V range, the voltage ripple on the auxiliary power supply output should be smaller than the hysteresis specification of LM5113 to avoid triggering device shutdown.

A local bypass capacitor should be placed between the VDD and VSS pins. And this capacitor should be located as close to the device as possible. A low-ESR, ceramic surface mount capacitor is recommended. TI recommends using 2 capacitors across VDD and GND: a 100-nF ceramic surface-mount capacitor for high frequency filtering placed very close to VDD and GND pin, and another surface-mount capacitor, 220-nF to 10- $\mu$ F, for IC bias requirements.

## 10 Layout

### 10.1 Layout Guidelines

Small gate capacitance and miller capacitance enable enhancement mode GaN FETs to operate with fast switching speed. The induced high  $dv/dt$  and  $di/dt$ , coupled with a low gate threshold voltage and limited headroom of enhancement mode GaN FETs gate voltage, make the circuit layout crucial to the optimum performance. Following are some hints.

1. The first priority in designing the layout of the driver is to confine the high peak currents that charge and discharge the GaN FETs gate into a minimal physical area. This will decrease the loop inductance and minimize noise issues on the gate terminal of the GaN FETs. The GaN FETs should be placed close to the driver.
2. The second high current path includes the bootstrap capacitor, the local ground referenced VDD bypass capacitor and low-side GaN FET. The bootstrap capacitor is recharged on a cycle-by-cycle basis through the bootstrap diode from the ground referenced VDD capacitor. The recharging occurs in a short time interval and involves high peak current. Minimizing this loop length and area on the circuit board is important to ensure reliable operation.
3. The parasitic inductance in series with the source of the high-side FET and the low-side FET can impose excessive negative voltage transients on the driver. TI recommends connecting the HS pin and VSS pin to the respective source of the high-side and low-side transistors with a short and low-inductance path.
4. The parasitic source inductance, along with the gate capacitor and the driver pulldown path, can form a LCR resonant tank, resulting in gate voltage oscillations. An optional resistor or ferrite bead can be used to damp the ringing.
5. Low ESR/ESL capacitors must be connected close to the IC, between VDD and VSS pins and between the HB and HS pins to support the high peak current being drawn from VDD during turnon of the FETs. Keeping bullet #1 (minimized GaN FETs gate driver loop) as the first priority, it is also desirable to place the VDD decoupling capacitor and the HB to HS bootstrap capacitor on the same side of the printed-circuit board as the driver. The inductance of vias can impose excessive ringing on the IC pins.
6. To prevent excessive ringing on the input power bus, good decoupling practices are required by placing low-ESR ceramic capacitors adjacent to the GaN FETs.

The following figures show recommended layout patterns for WSON-10 package and DSBGA package, respectively. Two cases are considered: (1) Without any gate resistors; (2) With an optional turnon gate resistor. It should be noted that 0402 DSBGA package is assumed for the passive components in the drawings. For information on DSBGA package assembly, refer to [Related Documentation](#).

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.
